

Core Focus

- Using the standard algorithm for multi-digit multiplication
- Solving word problems involving multiplication
- Building conceptual understanding of volume
- Working with the formula for calculating volume of prisms

Multiplication

- The standard algorithm provides a method for performing multi-digit multiplications that are difficult to do mentally, such as 42×34 .

3.2 Step In Reviewing Multiplication Strategies

Think about some of the different situations in which you use multiplication.

Imagine you have to buy carpet for this floor area. Look at how these students figured out the area to be covered.

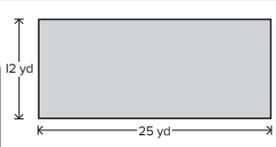

Anna used partial products.

$$10 \times 25 + 2 \times 25$$

David used factors.

$$12 \times 25 \text{ is the same as } (3 \times 4) \times 25$$

$$\text{and } (3 \times 4) \times 25 \text{ is the same as } 3 \times (4 \times 25)$$

In this lesson, students choose a familiar multiplication strategy to calculate multiplication problems.

- The standard algorithm is built on the same idea of multiplying part by part, using place value, and then adding all the separate parts together.

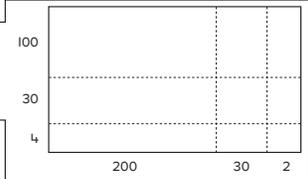

3.5 Step In Extending the Standard Multiplication Algorithm

The local park is rectangular and measures 134 yd by 232 yd. How could you figure out the area of the park?

Akeema drew this diagram of a rectangle split into parts to make it easier to multiply. Write the partial product inside each part of her diagram.

Add the partial products and write the area of the park below.

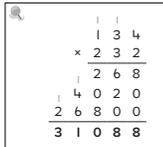

Area is yd²

Toby used the standard multiplication algorithm to calculate the area. What steps did he follow?

Look carefully at the first and third row of his calculations. What do you notice?

Why is the product in the third row 100 times greater than the product in the first row?

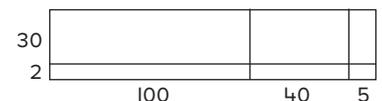

In this lesson, students connect the partial products strategy to the standard algorithm for multiplication.

Ideas for Home

- Work with your child on basic multiplication facts for a few minutes at a time, several days every week.
- Help your child identify the facts they just know, the facts they can figure out using a strategy (“I know 5×7 is 35, so 6×7 is seven more, or 42”), and those facts that are still challenging.
- If your child is making mistakes with the standard algorithm, ask them to solve the problem first by using the partial products strategy (rectangle model), or any method they prefer. Then work with them step by step to connect their answer to the algorithm.

Glossary

- ▶ The end result of multiplication is called the **product**.
- ▶ Students use an area model (rectangle) to find the **partial products** of a multiplication problem, such as 32×145 . Each partial product is then added together to find the product, in this case, 4,640.

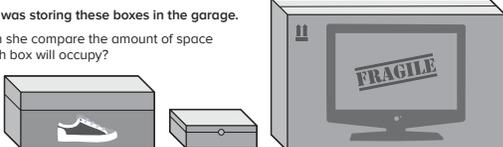

Volume

- The focus of this module is on the concept of volume (the amount of space that an object occupies).
- To think about the volume of an object (e.g. a box), students visualize filling it up with small cubes. The volume of the box is the number of cubes needed to fill it.
- Students visualize covering the base of an object with a single layer of small cubes, and then think about how many layers of cubes would be needed to fill up the shape.

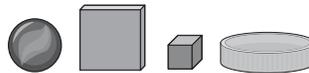

3.8 Step In Analyzing Unit Cubes and Measuring Volume

Jerilene was storing these boxes in the garage.
How can she compare the amount of space that each box will occupy?

To measure the space, she decides to fill each box with objects that are the same shape.
How will this help?

Look at these objects.
Which object would you use to measure the volume of each box?
How did you decide?

Jerilene chose to use centimeter cubes to find the volume of the jewelry box.
Does she need to fill the whole box with cubes?
What is an easier way to figure out the volume?

Just find the number of cubes in one layer. Then find the number of layers.

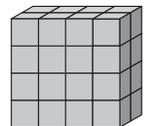

In this lesson, students investigate the volume of different boxes.

- Students eventually find the volume of prisms (boxes) by multiplying the area of the base by the height, which is the same as length \times width \times height.
- Students then work in reverse by starting with the volume of a prism and thinking about what its dimensions might be (i.e. three numbers that multiply to give the volume). E.g. if the volume of a prism is 30, possible dimensions include: $2 \times 3 \times 5$, and $1 \times 6 \times 5$.
- Students use what they have learned about the volume of prisms to solve a variety of real-world problems.

3.9 Step In Developing a Formula to Calculate Volume

How can you figure out the volume of this prism without counting each individual cube?

I know there are 8 cubes in the base. There are 4 layers. $8 + 8 + 8 + 8 = 32$.

Antonio multiplied the height of the prism by the number of cubes in the base.

Base	Height
8 cubes	4 layers
$8 \times 4 = 32$ cubes	
Volume is 32 cubes.	

Kuma multiplied the dimensions.

Length	Width	Height
4 cubes	2 cubes	4 cubes
$4 \times 2 \times 4 = 32$ cubes		
Volume is 32 cubes.		

How are their methods similar?
What rule could you write to match each method?

Look at Kuma's method.
Does it matter in what order she multiplies the dimensions?
How do you know?

Volume is usually measured in cubic units. The abbreviation for cubic centimeters is cm^3 .

In this lesson, students use small blocks to find the volume of rectangular prisms.

Ideas for Home

- Have your child collect different sized boxes from around your home (e.g. shoe boxes, cereal boxes, and gift boxes). Have your child measure the dimensions of the boxes (length, width, and height) to the nearest inch and then find the volume.
- Choose a small box from the activity above and ask, "What are the possible dimensions of a box large enough to fit 12 of these smaller boxes?" Encourage your child to draw a picture or diagram to help solve the problem.
- Ask your child to compare the volumes of the different boxes. Boxes that look very different can have similar volumes.
- Tell your child the volume of a rectangular prism (a box), and ask them to find the possible dimensions. E.g. if the volume is 36 cubic units, the dimensions could be $3 \times 3 \times 4$, or $2 \times 2 \times 9$. See how many solutions your child can find.

Glossary

- Volume** is usually measured in cubic units.

$$\text{cubic inches} = \text{in}^3$$

$$\text{cubic centimeters} = \text{cm}^3$$
